DEPARTMENT OF COMPUTER SCIENCE AND ENGINEERING

SLEEP DISORDER DIAGNOSIS PREDICTION USING MACHINE LEARNING
(FINAL REVIEW)

BATCH NO : 18

UNDER THE GUIDANCE OF

Mr.N.KARTHICKKUMAR (AP/CSE)

PRESENTED BY :

1. SANJAY R (730422104102)
2. SAMJAY KUMAR KP (730422104103)
3. VISHAL KUMAR YADAV (730422104123)

PROBLEM DOMAIN IDENTIFICATION & DETAILED ANALYSIS

DOMAIN : Health Care/Machine Learning

PROBLEM STATEMENT:

Sleep disorders are not just about feeling tired. They can lead to:

- Heart Disease (high blood pressure, heart attack, stroke)
- Diabetes & Obesity
- Depression & Anxiety
- Memory Loss & Poor Focus
- Nearly 1 in 3 adults suffer from insomnia or sleep apnea.

If ignored, sleep disorders can shorten lifespan and silently destroy quality of life.

ABSTRACT

- Sleep disorders including Insomnia and Sleep Apnea are increasingly prevalent conditions that significantly impact physical and mental well-being, yet often remain undetected until serious complications arise.

- This project proposes a machine learning-based prediction system that diagnoses sleep disorders using patient lifestyle and health data such as age, gender, BMI, blood pressure, sleep duration, stress level, and physical activity.

- Multiple classification algorithms including Random Forest, Decision Tree, SVM, KNN and Gradient Bossting are applied and compared for prediction accuracy.

- Feature importance analysis is performed to identify the most influential health parameters contributing to sleep disorder prediction.

- Experimental results demonstrate high prediction accuracy, providing a fast, cost-effective, and accessible alternative to clinical sleep testing.

INTRODUCTION

- Sleep is a fundamental biological necessity, and disruptions to normal sleep patterns have far-reaching consequences on an individual's health, cognitive performance, and overall quality of life.
- According to global health statistics, over 1 billion people suffer from some form of sleep disorder, with Sleep Apnea and Insomnia being the most common. Despite their prevalence, the majority of cases remain clinically undiagnosed.
- Conventional diagnostic techniques such as Polysomnography (PSG) are the gold standard for detecting sleep disorders but are expensive, require specialized equipment, and are limited to hospital settings.
- With the rapid advancement of machine learning and the availability of large-scale health datasets, it is now possible to build predictive models that identify sleep disorders using non-invasive, easily collectible data.

OBJECTIVE

- To develop a machine learning-based system that accurately predicts and classifies sleep disorders including Insomnia and Sleep Apnea from patient health and lifestyle data.

- To collect, preprocess, and analyze a real-world Sleep Health and Lifestyle Dataset comprising features such as age, BMI, blood pressure, sleep duration, physical activity, and stress level.

- To implement and compare multiple classification algorithms — Random Forest, Decision Tree, SVM, KNN, and Gradient Boosting — and identify the best-performing model.

- To perform feature importance analysis to determine which health parameters are the most significant predictors of sleep disorders.

- To build an interactive, user-friendly prediction interface that allows individuals to input their health data and receive an instant sleep disorder diagnosis.

- To provide an affordable and accessible alternative to expensive clinical sleep diagnosis methods.

7	CatBoost Classifier for Medical Diagnosis	Prokhorenko va et al.	Handles categorical features efficiently	Requires hyperparam eter tuning
8	IoT-based Sleep Monitoring System	Walch et al.	Real-time monitoring of sleep patterns	Privacy concerns with data collection
9	Comparative Study of ML Classifiers for Sleep Disorder Prediction	Hassan et al.	Benchmarks multiple algorithms fairly	No real clinical validation

EXISTING SYSTEM

- Existing sleep disorder diagnosis relies heavily on Polysomnography (PSG), an overnight lab-based sleep study. While accurate, it is costly and highly inconvenient for most patients.
- Questionnaire-based tools such as the Pittsburgh Sleep Quality Index (PSQI) and Epworth Sleepiness Scale (ESS) are paper or PDF based, with no interactive digital interface for instant results.
- Existing web health portals only provide general sleep-related information and tips — they do not offer any machine learning-powered diagnosis or personalized prediction for the user.
- Current ML research on sleep disorders focuses only on model building and accuracy comparison but does not deploy the model into a usable web application accessible to the general public.
- There is no existing responsive web system that combines a clean user interface with a trained ML backend to provide instant, accurate, and personalized sleep disorder predictions.

DISADVANTAGES OF EXISTING SYSTEM

- Polysomnography is extremely costly, requires overnight hospital stays, and is completely inaccessible to patients in rural or low-income settings.
- Questionnaire-based tools are static, subjective, and do not leverage any machine learning for accurate classification — results depend entirely on patient self-reporting.
- Existing health websites only provide generic information without any personalized prediction capability, making them insufficient for early diagnosis.
- Current ML-based research models are not deployed on any web platform, meaning the general public has no way to access or benefit from these prediction systems.
- None of the existing systems offer a responsive design, meaning they are not usable across different devices like mobile phones and tablets, limiting accessibility.

PROPOSED SYSTEM

- The proposed system is a responsive web-based Sleep Disorder Diagnosis application built using Python and Streamlit framework, which allows users to input their health and lifestyle details through an interactive web interface and receive instant sleep disorder predictions.

- The system trains and compares eight machine learning algorithms — Random Forest, Gradient Boosting, Support Vector Machine (SVM), K-Nearest Neighbors (KNN), Logistic Regression, Neural Network (MLP), AdaBoost, and Ensemble Voting — to identify the best-performing model for sleep disorder classification.

- The dataset includes health and lifestyle features grouped into four categories — Demographics (Age, Gender, Occupation), Sleep Metrics (Sleep Duration, Quality of Sleep), Health Indicators (BMI Category, Blood Pressure, Heart Rate), and Lifestyle (Physical Activity Level, Stress Level, Daily Steps).

- Blood Pressure is split into Systolic_BP and Diastolic_BP during preprocessing, and all features are normalized before being passed into the models for training and evaluation.

- The Ensemble Voting model is identified as the best model with a Cross-Validation Score of 93.3%, and it is deployed in the web application to provide real-time predictions for users.

ADVANTAGES OF PROPOSED SYSTEM

- The web-based approach makes the sleep disorder prediction tool accessible to anyone with an internet connection and a browser, without requiring any app installation or clinical visit.
- The fully responsive design ensures the system works seamlessly across all devices — desktop, laptop, tablet, and mobile — providing a consistent and user-friendly experience.
- By comparing eight different ML classifiers and deploying the best one, the system guarantees high prediction accuracy and reliable diagnostic output for users.
- The system is cost-free for users, scalable for large numbers of concurrent users, and can be easily updated with new training data or improved models without changing the frontend.

IMPLEMENTATION MODULE

Phase 1: Data Collection Module: The Sleep Health and Lifestyle Dataset is collected containing patient records with health and lifestyle attributes. Features include Demographics (Age, Gender, Occupation), Sleep Metrics (Duration, Quality), Health Indicators (BMI, Blood Pressure, Heart Rate), and Lifestyle factors (Physical Activity, Stress Level, Daily Steps).

Phase 2:Data Preprocessing Module: Missing values are handled, categorical variables are label-encoded, Blood Pressure is split into Systolic_BP and Diastolic_BP columns, and numerical features are normalized using StandardScaler to prepare clean data for model training.

Phase 3: Model Training & Selection Module: Eight machine learning algorithms are trained and compared.

Phase 4: Web Application Module (Frontend): The frontend is built using Python with Streamlit framework, providing a fully responsive and interactive web interface. Users can enter their health parameters through the web form and get instant predictions displayed on the same page.

Phase 5: Performance Evaluation Module: Each model is evaluated using Test Accuracy and Cross-Validation Score. The Ensemble (Best) model achieves a Cross-Validation Score of 93.3%. Feature importance analysis is performed using Random Forest to identify the most influential health parameters.

💡 Sleep Health Tips

Evidence-based recommendations for better sleep

🌙 Sleep Hygiene | 🍎 Lifestyle | 🧘 Relaxation | ⚠️ Warning Signs

🛏️ Optimize Your Sleep Environment

- **Temperature:** Keep your bedroom between 60-67°F (15-19°C)
- **Darkness:** Use blackout curtains or a sleep mask
- **Noise:** Consider white noise or earplugs
- **Comfort:** Invest in a quality mattress and pillows

⏰ Maintain a Consistent Schedule

- Go to bed and wake up at the same time daily
- Avoid sleeping in on weekends (max 1 hour difference)
- Create a 30-60 minute wind-down routine
- Limit naps to 20-30 minutes before 3 PM

📱 Manage Screen Time

- Avoid screens 1-2 hours before bed
- Use blue light filters on devices

Data Insights

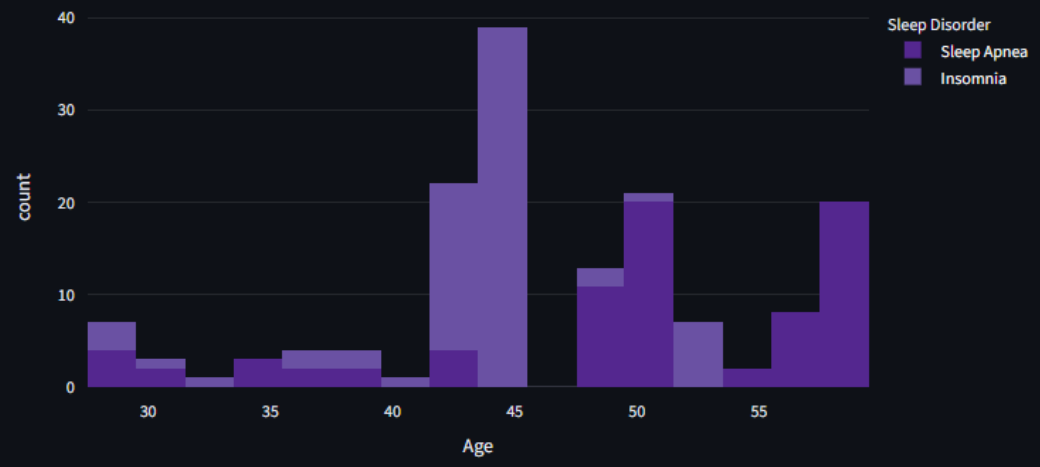
Age Distribution by Sleep Disorder



Future Enhancement

- The web application can be enhanced by integrating a user login and registration system, allowing individual users to save their prediction history and monitor changes in their sleep health over a period of time through a personalized dashboard.

- The current Ensemble Voting model can be further improved by incorporating advanced deep learning architectures such as LSTM (Long Short-Term Memory) networks to capture complex patterns in sleep-related health data and improve prediction accuracy beyond 93.3%.

- The system can be extended to support multi-class prediction beyond the current three categories (No Disorder, Insomnia, Sleep Apnea) by including additional sleep conditions such as Narcolepsy, Restless Leg Syndrome, and Circadian Rhythm Disorders for a more comprehensive diagnosis tool.

- Additional health parameters such as dietary habits, caffeine intake, alcohol consumption, mental health scores, and medication history can be incorporated into the model to further strengthen prediction reliability across diverse patient profiles.

Conclusion

- Comprehensive ML-Based Web Application: The proposed system successfully implements and compares eight machine learning algorithms — Random Forest, Gradient Boosting, SVM, KNN, Logistic Regression, Neural Network, AdaBoost, and Ensemble Voting — within a fully responsive Streamlit web application for accurate sleep disorder diagnosis.

- Best Model Performance: The Ensemble Voting model achieved the highest Cross-Validation Score of 93.3%, confirming that combining multiple classifiers produces more robust and reliable predictions compared to any single algorithm used independently.

- Meaningful Feature Insights: Feature importance analysis using Random Forest revealed that BMI Category, Systolic Blood Pressure, Diastolic Blood Pressure, Occupation, and Age are the top five most influential factors in predicting sleep disorders, providing clinically valuable insights for preventive healthcare.

- Multi-Page Web Platform: Beyond just prediction, the system offers a complete sleep health platform with dedicated pages for Model Analytics, Confusion Matrix, Feature Importance, Data Explorer, and Sleep Health Tips, making it useful and informative for both general users and researchers.
